Climatological Data for July, 1910. DISTRICT No. 12, COLUMBIA VALLEY.

EDWARD A. BEALS, District Editor.

July was the fifth consecutive month with a deficiency in precipitation, and while this month is ordinarily very dry there are usually a few days with rain in the driest sections, and moderate falls occur elsewhere. This year, however, over 100 stations reported no rain in measurable quantities, and the drought was so severe on the ranges as to cause a scarcity of feed and some suffering among stock, but no losses. The streams all became unusually low, as noted elsewhere, and navigation was suspended on the Snake River and on the upper stretches of the Willamette River. The forest floors became so dry that many fires were started, some by campers, some by lightning, some by sparks from locomotives, and in other ways until, near the end of the month, the sky was very smoky. The fires were most numerous and damaging in the Flathead country in Montana, the Colville country in Washington, and in and about the Coeur d'Alene section of Idaho. No very destructive fires occurred in Oregon, but a number of small ones broke out in the Blue Mountain Reserve in Wallowa County, and along both slopes of the Cascade Mountains, which required considerable attention, and many of them were still burning at the end of the month. In the Coast Range of Mountains the fires were mostly confined to slashings and second growth timber which burned furiously for a while without doing much damage. Most of the fires started during a dry spell between the 5th and 11th. Showery conditions prevailed on the 20th, 21st, and 22d, and many of the fires were either put out or checked at that time. Those that continued to burn, and those that started later, were aided by the dry weather which followed and at the end of the month the conditions were favorable for the spreading of the fires in all sections of the Columbia Valley. Three lives were lost by forest fires, and it is impossible to estimate the property loss which very likely has been greatly overestimated in the newspapers. It has been a long time since a season so favorable for forest fires has occurred, and that the losses are not greater is due to the organized effort that has been made to fight them. and to the laws that have been enacted with a view toward making people careful about putting out fires that have been started for necessary purposes.

TEMPERATURE.

The mean temperature, as determined from the records of 229 stations, was 67.7° , which is 0.7° above the district average. Along the coast of Oregon, and in Washington, west of the Cascade Mountains and also in the south central portion, the mean temperatures were generally below the normal. Elsewhere, with the exception of some local differences, the departures ranged usually above the seasonal average. The greatest departure below the normal was -5.5° at Fairview, Oreg., in the coast drainage area at an elevation of 142 feet, and the greatest departures above were in the extreme eastern portion of the district, where in western Montana and eastern Idaho the departures were, in some instances, as great as $+3.7^{\circ}$, $+4.2^{\circ}$, and $+4.7^{\circ}$.

The warmest sections were in the central portion of the Snake River Valley, where mean temperatures of 75° to 81° occurred, and along the central portion of the Columbia River course in Washington and Oregon, where the mean temperatures were 75° to 78°. The coolest sections were along the sea coast and in the elevated portions of the interior.

The weather was relatively cool during the first five days of the month and, except in the central portion, or that part lying between the Rocky and the Cascade mountains, from the 23d to the 31st, and the minimum temperatures for the month were generally recorded during the first or third decades.

In some localities in the interior freezing temperatures were recorded during these periods and frost formed. The warmest weather occurred throughout the district during the second decade, and in central sections also during the latter half of the third decade.

The highest mean temperature was 81.1° at Garnet, Idaho, on the watershed of the middle Snake, at an elevation of 2,575 feet, and the lowest was 54.0° at Tatoosh Island, in northwestern Washington, at an elevation of 86 feet. The highest recorded temperature was 110° at Garnet, Idaho, on the 13th, and also at Glenns Ferry, Idaho, on the 13th and 17th; both stations are in Elmore County, in the middle Snake basin, at elevations above 2,560 feet. The lowest recorded temperature was 22° at Range, Oreg., in the Blue Mountains at an elevation of 3,500 feet, on the 4th.

PRECIPITATION.

The average precipitation, as determined from the records of 338 stations, was 0.22 inch, which is slightly more than half an inch below the normal amount. The deficiencies were more than 1 inch in portions of the coast drainage area in northwestern Oregon, in portions of the coast and the Puget Sound drainage areas in northwestern Washington, and in the Columbia River Basin in northeastern Washington and in central western Montana. The only excesses occurred at Jacksonville, Oreg., in the Rogue River Basin, at an elevation of 1,640 feet; at La Grande, Oreg.. in the Blue Mountains, at an elevation of 2,784 feet; at Ovando, Mont., near the headwaters of the branches of the Columbia, at an elevation of 4,207 feet, and at Afton and Bedford, both in Uinta County, Wyo., in the upper Snake drainage basin, at elevations of 6,200 feet and 5,900 feet, respectively. In Oregon and Washington the precipitation occurred mostly from the 14th to the 22d, inclusive, but in the eastern sections of the district the rainfall was better distributed through the month, in Idaho, western Wyoming, northern Utah and northern Nevada, the rainless periods being, approximately, from the 5th to 11th, and from the 23d to 25th, while in Montana they were from the 5th to 7th, 10th and 11th, the 19th, and 24th to 28th.

The greatest monthly precipitation was 1.77 inch at Edie, Idaho, in the Lost River Basin, and none occurred at 56 stations, while 45 stations reported only a trace. The greatest 24-hour rainfall was 1.20 inch on the 20th at Grindstone, Oreg., in the Deschutes Basin, at an elevation of 5,000 feet. A fall of 1 inch occurred on the 4th at Cottonwood Creek, Idaho, on the Boise River watershed, at an elevation of 4,000 feet.

THE RIVERS.

The deficient rainfall over the district during July is shown in the quite uniformly decreasing river stages throughout the month. Streams in many sections were lower than they have ever been known to be before, for which reason the placer mining season was shorter than usual. Some lumber mills were compelled to shut down temporarily owing to there not being sufficient water in the streams to permit the floating of logs to the mills; and in some recently constructed irrigation ditches the flow of water was insufficient for agricultural purposes, the reserve supply being inadequate on account of the marked dryness of the present summer season.

The Columbia.—With one or two exceptions the present July stages along the Columbia River were the lowest mean stages recorded in 7 years, as determined from data for those stations having long records, while at The Dalles this was the first time such a low stage was reached in July. As compared with past years' records, the average for the month ranged between 2.9

feet below the normal at Celilo and 9.7 feet below at The Dalles, while at Umatilla the departure from average conditions was -3.9 feet; at Vancouver, -5.7 feet; at Wenatchee, -5 feet, and at Northport, -6.9 feet. As compared with the height of the water during the preceding month, the mean stage was 5.5 feet lower at Vancouver, 4.5 feet lower at Umatila, 6.2 feet lower at Wenatchee, and 6.5 feet lower at Northport. The river fell quite steadily throughout the month, and the lowest stages were recorded on the 30th or the 31st. Navigation continued unimpeded throughout the month.

The Snake.—The mean of the daily stages at the several stations for the month averaged 4.4 feet below that for June, and it was 5.4 feet below the normal for July. The water continued to fall steadily throughout the month, and the lowest stages were recorded on the 31st. At Lewiston, the river fell from a stage of 3.2 feet on the 1st to one of 0.6 foot on the 31st, and the mean stage was only 1.7 foot. None of the regular

steamboats operated on this river during July.

The Willamette.—The mean stage of the Willamette River ranged between 0.3 foot below the normal at Salem and 4.7 feet below at Portland, and was 0.8 foot below at Albany. The July mean stages were uniformly lower than those for the preceding month at all stations, being 0.7 foot lower at Albany, 1 foot lower at Salem, 1 foot lower at Wilsonville, and 5.3 feet lower at Portland. The greater difference as shown for Portland is due to the stage of the river at that place being influenced by the varying conditions of both the Columbia and the Willamette. As a rule there was a gradual decrease in the river stages at all stations throughout the month, the highest readings generally occurring on the 1st and the lowest on the 31st.

The upper Willamette is at the lowest stage ever kown since it has been used as a commercial highway. When the river is at a fairly good stage the boats go as far as Corvallis, usually spoken of as the "head of navigation," and during high water the steamboats are able to go through to Eugene, 52 miles above Corvallis, and 171 miles from Portland. The present low water prevents boats from making regular trips beyond Newberg, and as the time was favorable for such survey, officials of the Oregon City Transportation Company during the last of the month made the trip from Eugene to Newberg in a rowboat for the purpose of examining and recharting the shoals for the benefit of their boatmen.

MISCELLANEOUS PHENOMENA.

The prevailing winds for the month were from the west and, as a rule, the velocities were low. A strong southwest wind prevailed all over the State of Washington on the 21st; a maximum velocity of 42 miles, the highest for the month in this district, being recorded at Spokane.

The amount of sunshine received over the district was above the average for July; the percentage of possible sunshine being 76 at Portland, 65 at Seattle, and 88 at Spokane. During the first half of the month the atmosphere was clear, but later it

became quite smokey, due to numerous forest fires.

Severe thunderstorms occurred in eastern Oregon and southern Idaho on the 19th, 20th, and 21st, causing a loss of two lives and considerable property. Several forest fires were started by lightning and in many cases the storms were accompanied by hail. Killing frosts were reported at a few stations in high altitudes.

NEWS ITEMS.

By Edward L. Wells, Section Director, Boise, Idaho.

The contract has been let by the United States Reclamation Service for enlarging the main south side canal leading from the Boise River diversion dam to the Deer Flat Reservoir. The function of this canal is to supply lands lying directly under it and to feed the Ridenbaugh Canal and Deer Flat Reservoir. In its present condition this canal has a carrying capacity of less than 1,200 second-feet, but is to have an ultimate capacity

of about 2,500 second-feet for use of the new lands of the project, requiring a bottom width of earth section of 70 feet and a height of bank above canal grade of 12 feet with $1\frac{1}{2}$:1 side

In considering the question of enlargement of the canal to the full width, it has been found that certain of the 40-foot bottom width sections subject to excessive seepage and liability to breaks can be lined with concrete with about the same amount or less expenditure than the sections could be widened for and that such lined sections will have a carrying capacity equal to, if not greater than, the 70-foot bottom width earth sections. The total length of these sections amounts approximately to 36,000 linear feet of the canal. About 10,000 feet of the most dangerous stretches were lined during the fall of 1909, and it is proposed that the remaining distance will be completed in approximately equal amounts during the falls of 1910 and 1911, the most dangerous parts being finished this fall. With these dangerous sections of the canal lined with concrete, the canal will be in splendid condition to resist both seepage and serious interference from breaks.

With this work completed, the main canal will be able to serve the Deer Flat Reservoir and all the lands of the project as they are developed by extensions of the lateral system.

E. K. Taylor, General Manager of the Dry Creek Irrigation Project, gives the following notes relative to the same. The irrigation system contemplates the reclamation of 20,000 acres of desert land in T. 10 and 11 N., R. 24 E., B. M., as a private enterprise. Canals are already constructed to irrigate 2,500 acres of land. There is sufficient water in Dry Creek during the months of June and July, when the amount of snowfall during the preceding winter is normal, to irrigate 6,000 acres of land. The system, when completed, contemplates the construction of a storage reservoir, there being a natural reservoir site 4 miles from the land to be irrigated, where engineers estimate that a dam 150 feet high will store 42,360 acre-feet of water. The dam will be 60 feet long at the bottom, 115 feet long at a height of 100 feet, 400 feet long at a height of 128 feet, and 800 feet long at 150 feet.

Considerable attention is being given to the pumping of water for lands lying too high to be reached by gravity systems. A pumping plant has recently been installed by the Payette Heights Irrigation Company to reclaim about 4,000 acres of land just above the town of Payette, Idaho. The initial installation consists of Byron Jackson pumps driven by two 75-horsepower Fairbanks-Morse motors. It is planned ultimately to make use of 1,000 horsepower. The water is taken from the lower Payette Ditch, raised 130 feet and turned into the Payette Heights Ditch. There will be smaller units installed in the High Line Ditch to pump the water to still higher lands. The ditch and pumping plant were put in by the cooperation of the land owners. It is estimated that the water will cost about \$5 per acre per season. The land to be reclaimed is in the heart of the fruit belt.

Contracts have been awarded for the construction of the Jerome Reservoir of the Twin Falls North Side project. This reservoir will have a capacity of 150,000 acre-feet and will cost, approximately, \$500,000. The maximum height of the dam will be 40 feet.

The breaking of the temporary dam at Jackson Lake, Wyoming, caused some loss of water in Snake River.

A survey has recently been made for a reservoir site on Mann Creek in Washington County, Idaho, and it is reported that a satisfactory site has been found.

Plans are being made for two great irrigation systems in southern Idaho. One of these comprehends the reclamation of several hundred thousand acres in the Bruneau Valley by an extension and enlargement of the Twins Fall Canal. The water is to be provided by impounding the flood waters of Snake River in a gigantic reservoir above American Falls.

Another looks to the reclamation of a still larger tract lying between Boise and Mountainhome, with water stored at the head of the Salmon River and brought under the Sawtooth Mountains in a tunnel.

The United States Reclamation Service is making extensive surveys and test borings for reservoir sites in the Boise watershed to augment the water supply for the Payette-Boise project.

The question of drainage of irrigated lands is engaging the attention of engineers in southern Idaho. The United States Reclamation Service is constructing a drainage system for the North Side Minidoka Project, near Rupert, and steps are being taken to attend to the matter of drainage in the Pioneer Irrigation District. In close connection with this is the problem of water conservation. Mr. Don H. Bark, of the United States Department of Agriculture, is conducting an elaborate system of experiments looking to a more economical use of water.

Several small power plants are being constructed on the Payette River in Long Valley. One of these, at Tamarack Falls, will supply power to the town of Roseberry, and another at Van Wyck Falls will furnish power for Van Wyck, Crawford, and Thunder City.

REPORT ON THE ANNUAL RISE IN THE COLUMBIA RIVER, 1910.

By T. F. DRAKE, Assistant Observer, Portland, Oreg.

There are two principal causes that operate to produce the annual spring rise in the Columbia River: The accumulated depth of the winter's snow in the mountains and foothills at the close of the cold season, and the effect of the subsequent temperatures upon the melting of this snow. An abundance of snow in the higher levels at the end of winter, and an early spring with steady warm or mild weather, will obviously cause an earlier annual rise of approximately shorter duration, and higher river stages than usual, while, under similar snowfall conditions, if the temperatures of spring are divided into periods of alternately warm and cool spells, it is evident that the annual rise will extend through a longer period of time and the maximum stages reached will not be so great.

Reports received early in April from Weather Bureau sources indicated that the snowfall at the headwaters of the Snake River, in Idaho and Wyoming, and at the headwaters of the branches of the Columbia in Montana during the winter had been heavier than usual, while reports from the Canadian Meteorological Service showed less than the usual amount for the winter over the Columbia River watershed in British Columbia. The accompanying table shows the snowfall conditions that obtained at selected stations in Montana and Idaho during the principal snowfall months. The comparatively heavy snowfall of December, January, and February especially, is here shown, and it will be noted that the accumulated snow on the ground at the end of February was only about 6 inches less than the total snowfall for that month. A study of Tables 1 and 2, in connection with Table 3, will be very 74----9

interesting, since the chief conditions affecting the river stages are indicated in the tables in a manner that permits of their being readily seen and appreciated. It should, however, be borne in mind that the figures given for the depth of the snow blanket at the end of March, and also at the end of April, do not represent the amount of snow gathered in drifts in the canyons and ravines in the higher levels; otherwise it might be difficult to explain satisfactorily why the highest river stages occurred this year in May. It may be mentioned that snow fell in some localities as late as May in considerable quantities.

* No record.

In all sections the weather during March was comparatively mild, the temperatures being uniformly above normal, and much of the snow in the higher levels melted, while at low and moderate elevations the snow generally had all disappeared by the end of the month. The snow remaining in the mountains at the close of the month was well packed and in a favorable condition for slow melting and a gradual run-off later. The heavy rains of February and early March, combined with the abnormally warm weather of the latter month, resulted in unusually high water in all streams, and flood conditions obtained in many sections. As a consequence there was much apprehension among interested people, particularly wholesale firms located in the lower sections of Portland, farmers engaged in cultivating the lowlands along the lower Columbia, fishermen, and logging and lumber companies operating along the lower course of this river or its tributaries, fears being entertained that these earlier floods were indicative of a greater annual rise that probably would equal, if not exceed, the highest stages recorded. These fears were, however, partially allayed by our reports to the effect that much of the snow was already melted, while that remaining in canyons and ravines, and at high elevations, was favorably conditioned for melting slowly, consequently resulting in a gradual run-off.

Table 3 shows the temperature and precipitation conditions that obtained in those sections whose weather most strongly influences the volume of water in the Snake and the upper Columbia rivers, and hence contributes most to the variable stages of the lower Columbia.

^{*} Precipitation included in that of the next measurement.
* Temperature extremes are from observed readings of the dry bulb; means are computed from observed readings.
† Also on other dates.
† Separate dates of falls not recorded.
† Data are from standard instruments not supplied by the U. S. Weather Bureau.
† Instruments are read in the morning; the maximum temperature then read is charged to the preceding day, on which it almost always occurs.
Estimated by observer.
Precipitation for the 24 hours ending on the morning when it is measured.
T. Precipitation is less than 0.01 inch rain or melted snow.

a, b, c, etc., indicate, respectively, 1, 2, 3, etc., days missing from the record.
